Comentarios al artículo Leptospirosis in Campinas, São Paulo, Brazil: 2007-2014

Hans Ramón Quiroz Ruiz, Gisela Lizeth Arteaga Faya

Mr. Editor: We have read the article “Leptospirosis in Campinas, São Paulo, Brazil: 2007-2014”1 and congratulate the authors for an excellent contribution; their results indicate the presence of cases of leptospirosis and its associated factors such as the signs of rodents and rainfall in areas of low socioeconomic level. Thus, we would like to highlight a fact that draws attention mainly in Peru: the presence of the rodent Sciurus stramineus, known as the white-naped squirrel, whose natural habitat is the dry forests of northwestern Peru and whose species has been introduced to urban areas2, especially in some university campuses and public parks, without any restrictions. A study carried out in free populations of these squirrels in a zoo in Peru determined that 82.3% of the specimens had antibodies against leptospira, mainly serovar icterohemorrhagiae3, evidencing the importance that they can play as hosts and their potential role in leptospirosis transmission in universities and spaces with concentrated human populations.

An outbreak of leptospirosis has been reported after a flood in a location that does not commonly pose a risk of active transmission for the disease, such as urban university campuses; thus recognizing that natural disasters increase the risk of exposure to leptospires4. Given the above mentioned and due to the climatic peculiarity of northwestern Peru and its antecedents with the so-called El Niño phenomenon, which increases the probability of torrential rains and floods5, mainly in regions where there are universities with populations of squirrels running free on their campuses, we propose that there is a potential risk of cases of leptospirosis in universities that meet the indicated characteristics.
